1. INTRODUCCIÓN

En este Boletín se presentan las observaciones magnéticas registradas en el Observatorio Geomagnético de la Isla Livingston durante el año 2009 y la campaña antártica 2009-2010.

La instalación y operación del observatorio se enmarcaron en el Proyecto ANT95-0994-C03 del Programa Nacional de Investigación en la Antártida. Durante la campaña 1995-1996 se realizó el montaje de las cassetas que en la actualidad albergan la estación magnética, ubicada en la Base Antártica Española (BAE) Juan Carlos I de la Isla Livingston (Islas Shetland del Sur). Paralelamente, se procedió a la verificación de la estación magnética así como de los equipos de medida absoluta del campo geomagnético en el *Observatori de l'Ebre*. Una evaluación de la homogeneidad espacial de las variaciones registradas, así como de la particular anomalía magnética cortical en el observatorio pueden encontrarse en TORTA et al. (1999a). Durante la campaña 1996-1997 se instaló el variómetro, del que se tienen registros desde el 7 de Diciembre de 1996, y se procedió a la realización de las primeras medidas absolutas.

En los anteriores Boletines (TORTA et al., 1997a, 1998, 1999b; GAYA-PIQUÉ et al., 2000, 2002; MARSAL et al., 2003, 2004, 2005, 2006, 2007, 2008, 2009) se han ido resumiendo sucesivamente las medidas realizadas desde esa fecha hasta febrero de 2009. Cabe señalar que el observatorio se encuentra atendido sólo durante los meses del verano austral. De esta forma, nuestra actividad en la campaña antártica 2009-2010 quedó comprendida entre el 2 de Diciembre de 2009 y el 7 de Febrero de 2010. Sin embargo, el observatorio se deja en registro continuo automático durante los meses de Marzo a Noviembre, recuperándose los datos de este período al inicio de la campaña siguiente.

Los valores del campo registrados por el observatorio son transmitidos a través del satélite GOES-E hasta el nodo de información geomagnética (GIN) que INTERMAGNET posee en Ottawa. Los datos son recuperados posteriormente por el *Observatori de l'Ebre* y mostrados en su página web: www.obsebre.es/php/geomagnetisme.php

2. SITUACIÓN GEOGRÁFICA

La instalación del observatorio requirió la edificación de tres cassetas térmicamente aisladas y construidas con materiales amagnéticos. La zona de emplazamiento de la estación magnética fue definida después de un estudio realizado por el *Instituto Geográfico Nacional* (CASAS et al., 1992) durante la campaña 1990-1991. Los resultados del levantamiento magnético efectuado mostraron que el lugar más apropiado es la zona de Punta Polaca, situada al Oeste de las instalaciones de la BAE y a unos 350 m de distancia de ellas aproximadamente. Asimismo, el lugar se encuentra suficientemente alejado del conjunto de instalaciones de la BAE para que no existan riesgos de contaminación de los registros magnéticos debido a la influencia de la Base o a efectos antropogénicos. De las tres cassetas, una aloja los sensores de un magnetómetro vector cuyo sensor es un magnetómetro de protones (PVM); otra contiene la electrónica, el sistema de control y adquisición de datos; y la tercera alberga el magnetómetro para la realización de medidas absolutas. Durante la campaña 2007-2008 se incorporó una nueva caja que alberga un nuevo variómetro de tipo fluxgate triaxial.

Las coordenadas del pilar fundamental son las siguientes:

Latitud Geográfica	62°	39'	44" S
Longitud Geográfica	60°	23'	41" W
Latitud Geomagnética*	52°	50'	13" S
Longitud Geomagnética*	8°	57'	42" E
Altitud s.n.m.	19.4 m		

*Calculado a partir de la 11^a generación del IGRF para la época 2010.0.

A 460 m en dirección Este del pilar fundamental se clavó un jalón como marca de referencia para la determinación de la Declinación. El acimut determinado entre la línea pilar-jalón y el Norte Geográfico es 90° 52' 3.66".

3. INSTRUMENTOS Y OPERACIÓN

3.1. VARIÓMETROS

Los dos instrumentos principales de la estación magnética automática son el magnetómetro vector (PVM) y el fluxgate triaxial suspendido (modelo FGE), ubicados en sendas cajas.

El PVM está constituido por un magnetómetro de precesión de protones Geomag sm90r de efecto Overhauser que mide la intensidad total del campo (F). El sensor de este magnetómetro está montado en el centro de dos conjuntos de bobinas de Helmholtz mutuamente perpendiculares orientados respectivamente según las direcciones dadas por la Declinación e Inclinación locales. Al aplicar corriente a esas bobinas y medir la magnitud de los vectores resultantes, pueden obtenerse los cambios en la Declinación, D, y la Inclinación, I; el sistema se conoce como configuración $\delta D/\delta I$. La estación fue desarrollada por el Geomagnetism Group del *British Geological Survey* (BGS) en Edimburgo. Los detalles técnicos de la misma pueden encontrarse en RIDDICK et al. (1995), y una descripción resumida de su fundamento y operación en TORTA et al. (1997b) y en MARSAL et al. (2007).

El FGE, construido por el *Danish Meteorological Institute* (DMI) (ver detalles en Danish Meteorological Institute, 2006), incluye tres sensores fluxgate suspendidos dispuestos ortogonalmente sobre un soporte de mármol. En nuestro caso, el conjunto se orienta de acuerdo con los tres ejes magnéticos locales, H, D y Z. La salida analógica de este magnetómetro es digitalizada por medio de dos conversores A/D de 16 bits que se muestran a 1 y 0.1 Hz. El primero está configurado para un rango dinámico de 3200 nT y una resolución de 0.05 nT, mientras que el segundo posee un rango dinámico de 6400 nT y resolución 0.3 nT.

Tanto el muestreo de ambos variómetros como la sincronización de tiempo se realizan bajo control de hardware basado en un microcontrolador PIC 16F877 y un receptor GPS. Los procesos de adquisición, almacenamiento, monitorización y transmisión de datos se realizan por medio de software desarrollado en lenguaje C en un PC embebido sobre LINUX (TORTA et al., 2009). Estos elementos se encuentran ubicados en una tercera caja, que asimismo aloja la electrónica que permite suministrar corriente estable a las bobinas $\delta D/\delta I$ del PVM, así como la fuente de alimentación del conjunto de la estación. Como se ha dicho, los conversores A/D del magnetómetro FGE se muestran a frecuencias de 1 y 0.1 Hz, mientras que para el PVM se produce un ciclo completo de polarizaciones de las bobinas $\delta D/\delta I$ una vez por minuto.

3.2. MEDIDAS ABSOLUTAS

Para la realización de medidas absolutas se ha utilizado un DI-flux ELSEC 810A, que consta de un magnetómetro fluxgate cuyo sensor viene montado en un teodolito amagnético Zeiss 015B. La electrónica se encuentra en el exterior de la caja.

El procedimiento de observación está basado en la determinación de campo nulo para la obtención de D e I. Para eliminar los errores de colimación entre el sensor y el eje óptico del teodolito, así como los debidos al “offset” de campo nulo generados por la electrónica, se realizan observaciones en las cuatro posiciones posibles para cada elemento (ver, p.e., JANKOWSKI Y SUCKSDORFF, 1996, TORTA et al., 1997b, o MARSAL Y TORTA, 2007).

Para la determinación contemporánea de la intensidad total (F) se extraen los valores correspondientes de la secuencia de medidas del PVM cuando éste mide con las bobinas sin polarizar. Para su reducción a la posición del pilar fundamental se han efectuado varias series de medidas en el mismo con el magnetómetro de precesión de protones Gem Systems GSM19 de efecto Overhauser. Durante la campaña 2008-2009 tales medidas han proporcionado una diferencia promedio de -1.3 nT (Fpilar fundamental - Fmagnetómetro vector).

4. PROCESO DE LOS DATOS

El proceso de datos preliminar incluye la detección y eventual eliminación de valores esporios por comparación de los valores de ambos variómetros. Tras la compilación de la serie de medidas absolutas, se ha procedido a la determinación de las líneas de base definitivas.

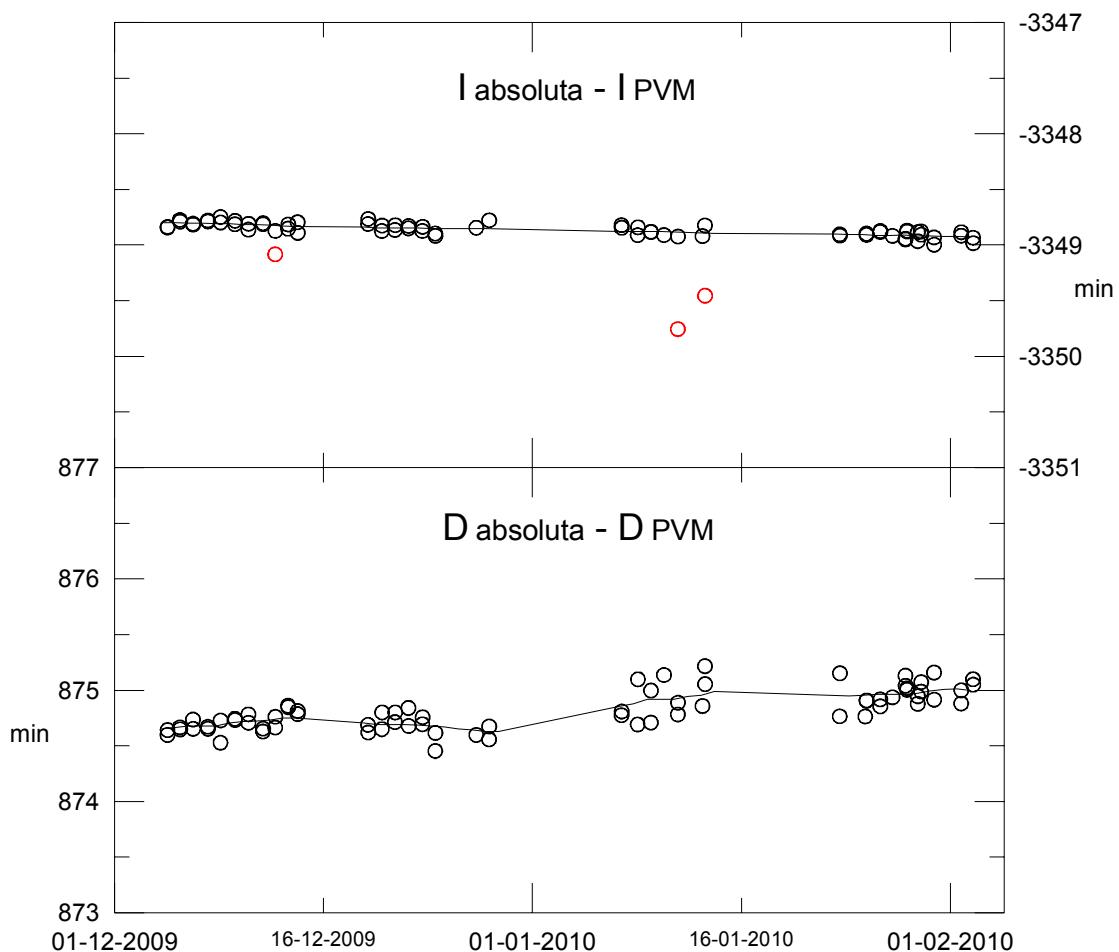

Fig. 1. Diferencias observadas entre el DI-flux y el PVM (círculos) y líneas de base adoptadas (líneas continuas) para los dos elementos D e I. Los círculos en rojo corresponden a las diferencias descartadas antes de la adopción de la línea de base. Período correspondiente a la campaña 2009-2010.

El procedimiento seguido ha sido:

Para cada elemento observado D e I se han substraído de los valores de las medidas absolutas los valores correspondientes del PVM por un lado y del FGE por otro (diferencias o líneas de base observadas). Sobre estas dos series de diferencias se ha realizado un análisis secuencial que finaliza con la obtención de las líneas de base (diferencias adoptadas). Este proceso incluye el análisis de ciertos observables que determinan la validez de las medidas absolutas individuales, el descarte de los valores de línea de base observada con diferencias excesivas, y una interpolación de los datos no rechazados del tipo que se decida más oportuno según el caso, ya sea una media móvil, un ajuste lineal, cuadrático, etc. Las diferencias observadas y las correspondientes líneas de base adoptadas para el PVM se ilustran en la Fig. 1 para la campaña 2009-2010.

Tras añadir las líneas de base a las medidas de los variómetros (y así trasladarlas a las referencias absolutas) se han producido los valores minuto del PVM y los valores de 1 y 10 segundos del magnetómetro FGE. Sin embargo, los valores del campo magnético para un instante dado no coinciden en ambas series al nivel de precisión que sería deseable, dado que ambos variómetros tienen propiedades distintas. Así, se ha optado por considerar el PVM como instrumento semiabsoluto, es decir, estable a medio y corto plazo (hasta varias semanas o incluso meses), mientras que la mayor resolución, precisión y frecuencia de muestreo del FGE lo hacen apto para la medición precisa de variaciones magnéticas a altas frecuencias; sin embargo, sus medidas (térmicamente sensibles) se encuentran afectadas ligeramente por la onda térmica diurna y en mayor grado por la onda térmica anual (Marsal et al., 2009), pues no se dispone de medios para estabilizar la temperatura de la caja que lo aloja. De este modo, se reducen los datos del magnetómetro FGE a los datos “semidefinitivos” del PVM, obteniendo así datos definitivos que conjugan las mejores propiedades de ambos instrumentos. Este proceso se realiza trasladando la media móvil de los datos del FGE en una ventana de cien minutos a la correspondiente media móvil del PVM en la misma ventana temporal. En resumen, se utiliza el DI-flux como instrumento absoluto para referenciar los datos del PVM en un primer paso, y a su vez se usan dichos datos “semidefinitivos” del PVM como datos semiabsolutos para reducir los datos del FGE en un segundo paso. De los valores minuto así derivados se obtienen fácilmente los magnetogramas y las tablas de medias que se presentan a continuación.

Teniendo en cuenta la conducta manifestada durante las últimas campañas en las que se han realizado medidas absolutas, las líneas de base que se han adoptado para el período entre ellas obedecen a funciones lineales con las pendientes necesarias para pasar de las diferencias adoptadas al final de una campaña a las del principio de la siguiente (Fig. 2).

Aunque la evolución de las líneas de base durante el período sin medidas absolutas es desconocida, cabe resaltar su considerable estabilidad interanual a lo largo de los últimos años. Teniendo en cuenta que una variación de 1 minuto de arco en declinación equivale a una variación de 5.8 nT en la dirección del Este magnético, la deriva invernal de la línea de base de esta componente ha sido inferior a 2 nT. Equivalentemente, una variación de 1 minuto de arco para la inclinación magnética supone un cambio de 8.5 y 5.8 nT en las intensidades horizontal y vertical (H y Z) respectivamente, lo que se traduce en una variación total del orden de 2 nT para H y 1 nT para Z.

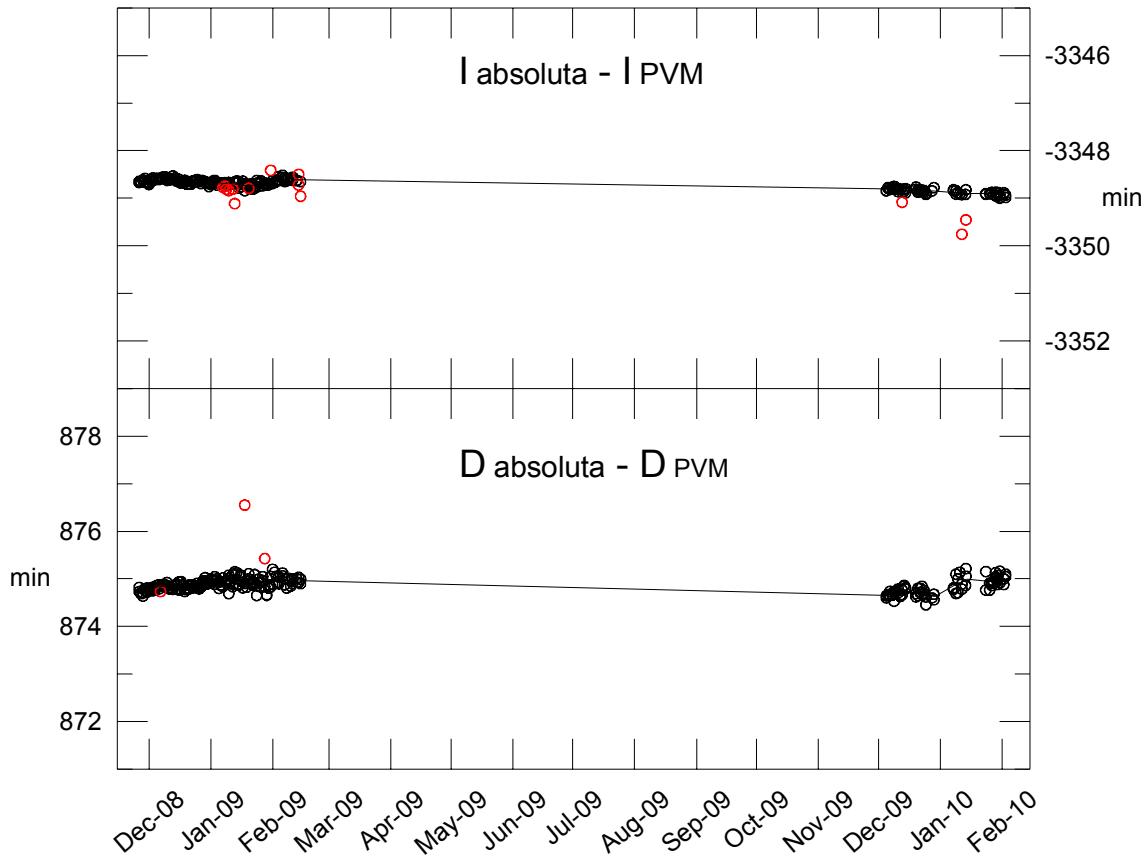

Fig. 2. Equivalente a la figura anterior para el periodo completo de registro desde noviembre de 2008 hasta febrero de 2010.

5. INCIDENCIAS

En este apartado se relacionan las incidencias más importantes que afectan a los datos, ocurridas durante el periodo que abarca este boletín. Los periodos no mencionados disponen de un registro normal.

- 1- Debido al deterioro del sistema de adquisición de energía de la base, en el periodo comprendido entre el día 10 de mayo y el 7 de junio de 2009 el PVM deja de adquirir datos. Esto da lugar a una mayor incertidumbre en los datos finales, puesto que se asume que los registros del FGE son más sensibles a variaciones de temperatura. De todos modos, la amplitud de la onda térmica diurna suele estar comprendida entre 1 y 2 °C en el interior del sensor FGE, lo que da lugar a un error máximo de 0.5 nT en los datos finales de los distintos componentes del campo (suponiendo un coeficiente de temperatura de 0.25 nT/°C dado por el fabricante).
- 2- Por las mismas razones anteriores, a partir del 7 de junio de 2009 se pierde todo registro de la estación hasta el inicio de la campaña 2009-2010, concretamente el 4 de diciembre de 2009.
- 3- Entre los días 24 de diciembre de 2009 y 4 de enero de 2010 se desmantela el magnetómetro FGE para apantallarlo a fin de evitar las interferencias producidas por una estación de radio cercana.
- 4- Entre el 31 de diciembre de 2009 y el 6 de enero de 2010 se produce una avería en el PVM. Sin embargo, entre los días 4 y 6 de enero se dispone de datos de F del magnetómetro de protones. Con ellos se corrigen parcialmente los datos del FGE.
- 5- Entre el 14 y el 23 de enero de 2010 se produce una segunda avería en el PVM, con lo que se obtienen datos definitivos a base de reducir directamente los valores del FGE al

pilar fundamental. Como en la incidencia 1, la cota máxima de error asociada a la penetración de la onda térmica diurna dentro del sensor FGE se estima en 0.5 nT.

Como consecuencia de las incidencias 3 y 4, entre los días 24 y 29 de diciembre de 2009 se obtienen datos definitivos a partir de los valores del PVM reducidos directamente al pilar fundamental, con lo que se pierden los registros de alta frecuencia (1 y 0.1 Hz) proporcionados por el magnetómetro FGE.

6. PRESENTACIÓN DE LOS DATOS

Los valores medios anuales para todos los elementos del campo obtenidos hasta la publicación de este Boletín se presentan en la tabla 1. Puesto que las líneas de base adoptadas en la Fig. 2 para el período sin medidas absolutas podrían diferir de las reales, damos en la tabla 2 las medias correspondientes únicamente a los períodos con referencias absolutas. Corresponden básicamente a las medias sobre los meses de Diciembre, Enero y Febrero de cada campaña. Las medias correspondientes a la época 2009.5 no se presentan debido a la falta de datos durante 6 meses (7 de junio a 4 de diciembre de 2009).

Año	D	H	Z	X	Y	I	F

Tabla 2. Valores medios para los períodos con referencias absolutas

Los datos que se presentan a continuación son:

- i) Índices K, calculados automáticamente mediante el método FMI, según una modificación del programa original (en lenguaje C) creado por P. McFadden (AGSO). Q y D indican los cinco días Internacionales de Calma y Perturbados de cada mes, respectivamente.
- ii) Magnetogramas diarios de la declinación (D), intensidad horizontal (H) e intensidad vertical (Z), mostrados secuencialmente y por meses.
- iii) Magnetogramas diarios de la intensidad total (F), mostrados secuencialmente y por meses.
- iv) Tablas mensuales de los valores medios horarios de D, H, Z y F. Todas las medias han sido calculadas a partir de valores minuto.

Los datos definitivos instantáneos de 1 y 10 segundos, así como las medias minuto, horarias, diarias y mensuales pueden encontrarse en los centros mundiales de datos (WDC) y en la web del *Observatori de l'Ebre*: www.obsebre.es/php/geomagnetisme.php.

Agradecimientos. Estos resultados forman parte de los Proyectos y Acciones especiales o complementarias ANT95-0994-C03, ANT97-1863-E, ANT98-0886, ANT-981604-E, REN2000-0833, REN2000-2468-E, REN2003-08376-C02-02, CGL2005-24190-E/ANT, CGL2006-12437-C02-02 y CTM2008-03033-E de los sucesivos Planes Nacionales de I+D+I del Ministerio de Ciencia e Innovación. Además de los autores de este Boletín, forman o han formado parte de los grupos investigadores las siguientes personas: L. F. Alberca, D. Altadill, E.M. Apostolov, C. Bianchi, I. Blanco, E. Blanch, J.O. Cardús, B. Casas, J.J. Curto, A. García, L.R. Gaya-Piqué, J. Merino, E. Sanclement, A. De Santis, J. Seguí y A. Ugalde. Los autores desean expresar su más sincero agradecimiento al personal técnico y científico de la BAE en las distintas campañas desde que se instaló el Observatorio, así como al Servicio Geográfico del Ejército por la determinación de posiciones y acimuts, y al Geomagnetic Laboratory del *Geological Survey of Canada*, en Ottawa, por la recepción y gestión de los datos transmitidos a través del satélite GOES-E. El apoyo técnico recibido por parte del Global Seismology and Geomagnetism Group del *British Geological Survey*, especialmente por parte de Christopher W. Turbitt y Simon Flower, ha resultado ser también fundamental. Mención aparte merece John C. Riddick, ex-miembro del mismo grupo, sin la colaboración del cual habría sido imposible llevar a cabo la renovación de la estación.

1. INTRODUCTION

In this Bulletin we give details of the magnetic observations recorded at the Livingston Island Geomagnetic Observatory during 2009, including the 2009-2010 austral summer survey.

Both the observatory installation and operation were on behalf of the National Program for Antarctic Research Project ANT95-0994-C03. In order that this objective could be achieved, during the 1995-1996 survey, the magnetic observatory instrument accommodation was deployed at the Spanish Antarctic Station Juan Carlos I (Livingston Island in the South Shetland Island group). In parallel with this work both the variometer station and the absolute observing instruments were tested and calibrated at Ebre Observatory, Roquetes, Tarragona, Spain. An assessment of the spatial homogeneity of the recorded variations, as well as of the particular observatory crustal anomaly biases are given in TORTA et al. (1999a). Both the variometer, deployed in a set of $\delta D/\delta I$ coils and the absolute instruments were installed during December 1996, with continuous recording and the absolute observing program beginning on December 7, 1996.

In the previous Bulletins (TORTA et al., 1997a, 1998, 1999b; GAYA-PIQUÉ et al., 2000, 2002; MARSAL et al., 2003, 2004, 2005, 2006, 2007, 2008, 2009) the measurements made between that date and February 2009 were summarized. As this site is only manned during the Austral summer all scientific staff departs at the end of February each survey, but the magnetometers are left recording and we retrieve the data recorded throughout the winter at the beginning of the next survey season. Thus, our activity during the 2009-2010 survey covered the period between December 2, 2009 and February 7, 2010.

Data recorded at the Observatory are transmitted via GOES-E satellite to the INTERMAGNET Geomagnetic Information Node (GIN) at Ottawa, being them afterwards retrieved by Ebre Observatory and made available in its website: www.obsebre.es/php/geomagnetisme.php

It is possible to obtain more information applying to:

<i>Observatori de l'Ebre Antarctic Data 43520 Roquetes (Tarragona)</i>	<i>Tel.: 977 50 05 11 Fax: 977 50 46 60 e_mail: smarsal@obsebre.es jmtorta@obsebre.es</i>
--	---

2. POSITION

The installation of the observatory required the erection of three thermally isolated huts which had been prefabricated using non-magnetic materials. The location of the observatory was determined using the results of a study made by the Instituto Geográfico Nacional (CASAS et al., 1992) during the 1990-1991 field season. The results of this magnetic survey showed the most appropriate site to be around the area named as Punta Polaca, located to the west of the Station settlement and at approximately 350 m from the main base. Located at this position, the site is far enough from the settlement to avoid man-made disturbances. One hut houses the Proton Vector Magnetometer (PVM); the second contains the control electronics and the data acquisition system; and the third accommodates the D/I fluxgate theodolite for the absolute observations. During the 2007-2008 survey a new hut was added up, which houses a tri-axial fluxgate magnetometer.

The coordinates of the absolute pillar are:

<i>Geographic latitude</i>	<i>62° 39'</i>	<i>44" S</i>
<i>Geographic longitude</i>	<i>60° 23'</i>	<i>41" W</i>

<i>Geomagnetic latitude*</i>	52°	$50'$	$13''$ S
<i>Geomagnetic longitude*</i>	8°	$57'$	$42''$ E
<i>Height above msl</i>	19.4 m		

* Computed from the 11th Generation of IGRF for the epoch 2010.0.

At a position 460 m to the west of the absolute pillar a fixed mark was constructed which is used as the reference mark in the determination of declination. The angle viewed from the D/I pillar between the azimuth mark and the geographic north (the azimuth of the mark) is $90^{\circ} 52' 3.66''$.

3. INSTRUMENTS AND OPERATION

3.1. VARIOMETERS

The two main instruments in the automatic magnetic observatory are a Proton Vector Magnetometer (PVM) and a suspended tri-axial fluxgate (model FGE), located in their respective huts.

The PVM is made up of a Geomag sm90r Overhauser magnetometer used to measure total field intensity (F). This magnetometer is deployed at the centre of a pair of dual axis Helmholtz coils which are deployed parallel to the directions given by the local declination and inclination. By applying bias currents through these coils and measuring the resultant vectors, changes in declination, D , and inclination, I , may be obtained; this is known as the $\delta D/\delta I$ configuration. The equipment was developed by the Geomagnetism Group of the British Geological Survey (BGS) in Edinburgh. Its technical details are described by RIDDICK et al. (1995), and a summarized description of its principles and operation by TORTA et al. (1997b) and MARSAL et al. (2007).

The FGE, made by the Danish Meteorological Institute (DMI) (see details in Danish Meteorological Institute, 2006), includes three suspended fluxgate sensors arranged orthogonally on a stable support made of marble. In our case, this trihedron is oriented by the variometer frame in the direction of the local magnetic axes, H, D and Z. The analog output of this magnetometer is digitized by means of two 16-bit A/D converters, which sample at both 1 and 0.1 Hz frequencies. The first one is set to a dynamic range of 3200 nT and a resolution of 0.05 nT, while the second has a dynamic range of 6400 nT and a resolution of 0.3 nT.

All sampling and timing are carried out under the control of hardware based on a PIC 16F877 microcontroller and a GPS receiver. The data acquisition, storage, monitoring and transmission processes are supervised using control software developed in C-language, which runs on a low power LINUX-based embedded PC. These elements are located in a third hut, which also accommodates the electronics which generates stable currents to the $\delta D/\delta I$ bias coils of the PVM, as well as the power supply for the whole station. As pointed out above, the A/D converters are sampled at both 1 and 0.1 Hz frequencies, while a complete cycle of polarizations of the PVM $\delta D/\delta I$ coils is produced every minute.

3.2. ABSOLUTE OBSERVATIONS

For the absolute measurements of declination and inclination an ELSEC 810A D/I-fluxgate theodolite is used. It comprises a single axis fluxgate magnetometer sensor element mounted on a Zeiss 015B nonmagnetic theodolite with the electronics package placed outside the hut.

The D/I observation procedure is based on the null-field technique to measure D and I . To remove the errors due to the misalignment of the magnetic axis of the fluxgate and the optical axis of the theodolite, as well as those due to the zero-field offset generated by the control

electronics, the observations are made in four positions for each element (see, e.g., JANKOWSKI & SUCKSDORFF, 1996, TORTA et al., 1997b, or MARSAL & TORTA, 2007).

The total field intensity (F) values are obtained from the PVM when it measures without polarizing the coils. For their reduction to the D/I pillar, several series of simultaneous measurements have been made using a Gem Systems GSM19 Overhauser proton precession magnetometer on it. These measurements gave a mean difference of -1.3 nT (Fabsolute pillar - Fvector magnetometer) for the 2009-2010 survey.

4. DATA PROCESSING

The preliminary data processing included the detection and elimination of any spikes in the data by comparing the values obtained with both variometers. After the compilation of the absolute measurements series, the definitive baselines were determined

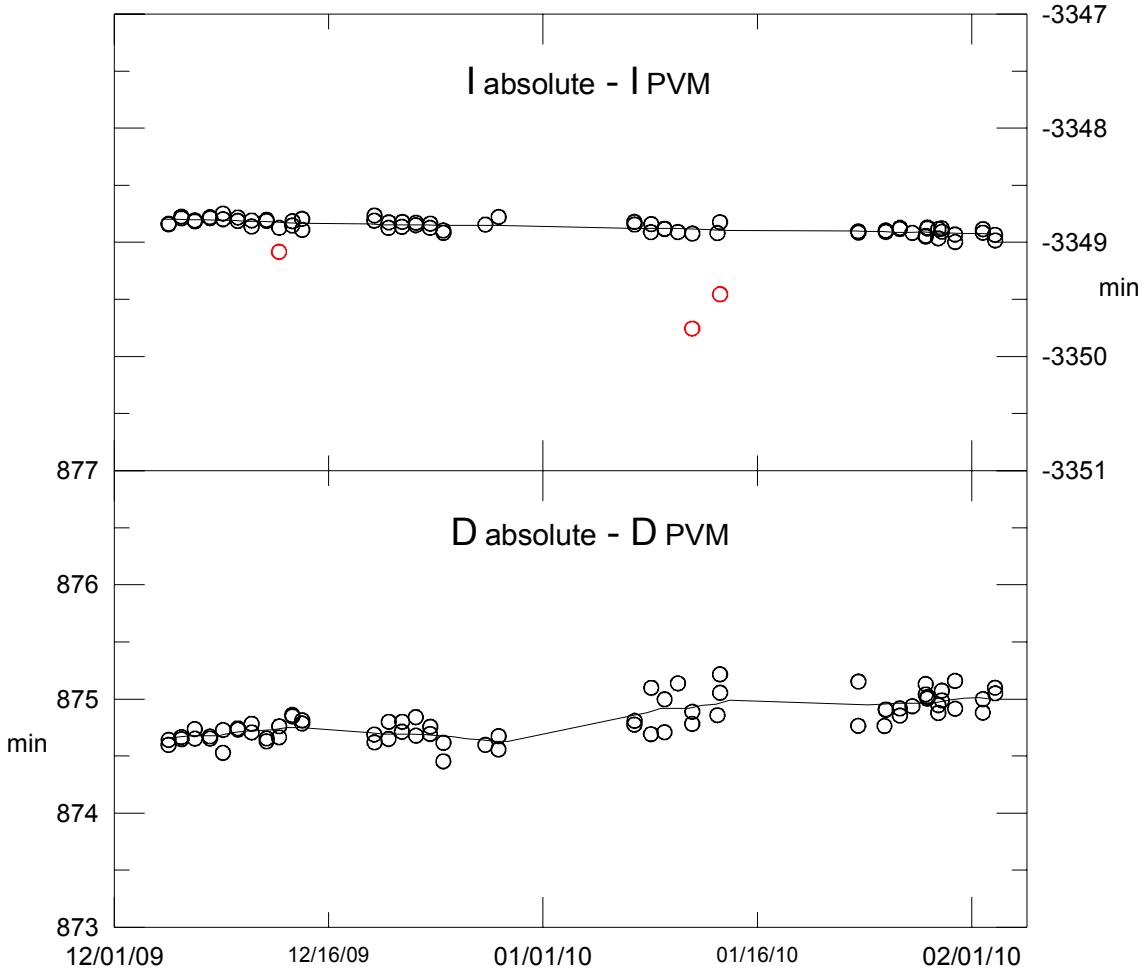

Fig. 1. Observed differences between the D/I-fluxgate and the PVM (circles) and adopted baselines (lines) for the two elements I and D. Red circles correspond to differences removed before the adoption of the baseline. Period corresponding to the 2009-2010 survey.

Following procedure was adopted to allocate the baselines:

For each observed element D and I, the absolute measurements were subtracted from the corresponding values of the PVM on the one hand, and from the FGE values on the other hand

(observed differences or observed baselines). To these two series of differences a sequential analysis was applied towards the determination of the adopted differences or adopted baselines. This process included an analysis of a series of observable quantities that determine the validity of the individual absolute measurements, the rejection of the observed baseline values with excessive differences, and the most suitable interpolation of the accepted data as the case may be: a running average, a linear or square fitting, etc. The observed differences and the corresponding adopted baselines for the PVM are plotted in Figure 1 for the 2009-2010 survey.

By adding the baselines to the vector magnetometer values (and thus translating the vector data to the absolute references) both the definitive minute values of the PVM and the 1- and 10-second values of the FGE magnetometer were produced. However, the magnetic field values of both data series for a given moment did not coincide at the desirable level of accuracy, as both instruments have different properties. Thus, we considered the PVM as a semi-absolute instrument, i.e., stable in the short and medium term (up to several weeks or even months), while the higher resolution, accuracy and sampling frequency of the FGE make it suitable for the precise measurement of the high-frequency magnetic field variations; nonetheless, its measurements (thermally sensitive) are slightly affected by the diurnal thermal wave and, to a larger extent, by the annual thermal wave (Marsal et al., 2009), since no means of temperature stabilization are available in the FGE hut. In this way, the FGE magnetometer data are reduced to the ‘semi-definitive’ data obtained from the PVM, giving rise to definitive data that combine the best properties of both instruments. This process consists of translating the running average of the FGE in a time window of one-hundred minutes to the corresponding running average of the PVM in the same time window. In summary, the D/I-fluxgate is used as the absolute instrument to reference the PVM data in a first step, and in turn such PVM ‘semi-definitive’ data are used to reduce the FGE data in a second step. The magnetograms and the tables of means which are presented below were obtained from these values.

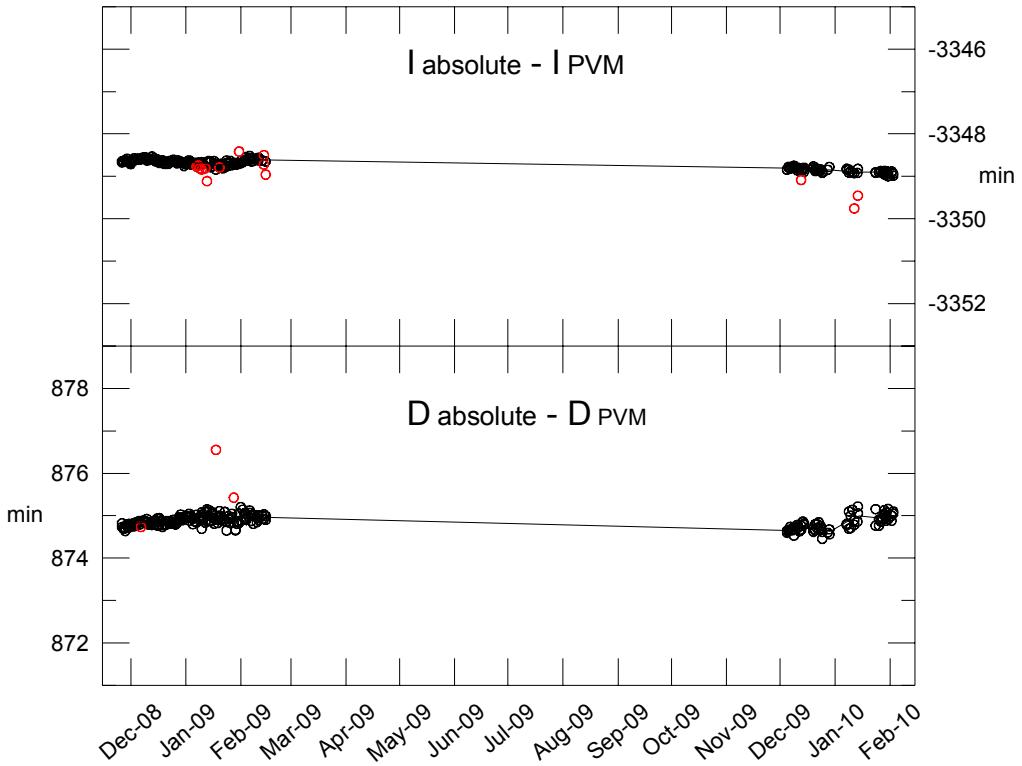

Fig. 2. As the previous figures but for the complete recording period from November 2008 to February 2010.

Taking into account the behaviour exhibited during the last surveys in which absolute measurements were made, the baselines adopted for the period in between are linear functions with the necessary slopes to pass from the adopted differences at the end of the penultimate survey to those at the beginning of the last one (Figure 2).

Although the baselines evolution during the period without absolute control is unknown, its present year-to-year stability should be noted. Taking into account that a change of one minute of arc in declination means a variation of 5.8 nT in the East magnetic direction, the drift of the baseline of this component for the last winter season was less than 2 nT. Equivalently, a variation of one minute of arc in the magnetic inclination entails a change of 8.5 and 5.8 nT in the horizontal and vertical intensities (H and Z) respectively, which means a total variation of about 2 nT for H and 1 nT for Z.

5. INCIDENCES

In this section we list the most important incidences on the data occurring on the time span to which this bulletin corresponds. The remaining periods have normal recording.

- 1- *Due to problems affecting the energy acquisition system in the Base, PVM data were not available in the period between May 10th and June 7th, 2009. This gives rise to additional uncertainty in the final data, since the available FGE data are assumed to be more sensitive to temperature variations. However, the amplitude of the diurnal thermal wave in the FGE sensor is within 1 and 2 °C, which gives rise to a maximum error of 0.5 nT in the final components of the magnetic field (assuming a thermal coefficient of 0.25 nT/°C given by the manufacturer).*
- 2- *For the same stated above reason, all geomagnetic records are lost from June 7th 2009 until December 4th 2009, at the beginning of the last summer survey.*
- 3- *Between December 24th 2009 and January 4th 2010 the FGE magnetometer was dismantled in order to shield it against the interferences produced by a nearby broadcasting station.*
- 4- *Between December 31st 2009 and January 6th 2010 a failure of the PVM was produced. However, between January 4th and 6th Proton F values were available, which permitted partial correction of the FGE measurements.*
- 5- *Between January 14th and 23rd 2010 a second failure of the PVM was produced. During this period, definitive values are directly obtained by reducing FGE values to the fundamental pillar. Similar to the case of incidence 1, an upper limit for the error associated to the penetration of the diurnal thermal wave into the FGE sensor is estimated at 0.5 nT.*

As a consequence of incidences 3 and 4, between December 24th and 29th 2009 definitive data are directly obtained by reducing the PVM data to the fundamental pillar. This causes a loss of the higher sampling rate (1 and 0.1 Hz) data provided by the FGE magnetometer.

6. PRESENTATION OF DATA

The annual mean values for all magnetic elements obtained until the publication of this Bulletin are presented in table 1. Since the adopted baselines of figure 2 for the period without absolute measurements might differ from the actual ones, we give in table 2 the means corresponding to only the periods with absolute references, basically corresponding to the means over December, January and February of each Survey. The means corresponding to the 2009.5 epoch are not presented because of the lack of data during 6 months (June 7th – December 4th, 2009).

Year	D	H	Z	X	Y	I	F

Table 2. Mean values for periods with absolute references.

The data presented following in this bulletin are:

- i) Computer-produced K indices by means of the FMI method, according to a modification of the original C-language program created by P. McFadden (AGSO). Q and D refer to the five International Quiet and Disturbed days in each month, respectively.
- ii) Month-at-a-glance daily magnetograms of declination (D), horizontal intensity (H) and vertical intensity, (Z).
- iii) Month-at-a-glance daily magnetograms of total intensity (F).
- iv) Monthly tables of hourly mean values of D, H, Z and F. All means have been calculated from minute values.

Definitive 1- and 10-second spot values, as well as 1-minute, hourly, daily and monthly mean values are available in the World Data Centres (WDC) and in the Ebre Observatory website: www.obsebre.es/php/geomagnetisme.php.

Acknowledgments. These results are part of the Research Projects ANT95-0994-C03, ANT97-1863-E, ANT98-0886, ANT98-1604-E, REN2000-0833, REN2000-2468-E, REN2003-08376-C02-02, CGL2005-24190-E/ANT, CGL2006-12437-C02-02 and CTM2008-03033-E, PN I+D+I, Spain. In addition to the authors of this Bulletin, the following people are or have been part of the research groups of these projects: L. F. Alberca, D. Altadill, E.M. Apostolov, C. Bianchi, I. Blanco, E. Blanch, J.O. Cardús, J.J. Curto, B. Casas, A. García, L.R. Gaya-Piqué, J. Merino, E. Sanclement, A. De Santis, J. Seguí and A. Ugalde. The authors would like to express their deep thanks to the technical and scientific staff of the Spanish Antarctic Station from the time the observatory was deployed and to the Servicio Geográfico del Ejército for the measurement of positions and azimuth bearings and to the Geomagnetic Laboratory of the Geological Survey of Canada, in Ottawa, for receiving and managing the transmitted data through GOES-E satellite. The technical support received from the Global Seismology and Geomagnetism Group of the British Geological Survey, especially from Christopher W. Turbitt and Simon Flower, have also turned out to be fundamental. Special mention deserves John C. Riddick, ex-member of the same group, without whom the upgrading of the system would have been impossible.

Livingston Island

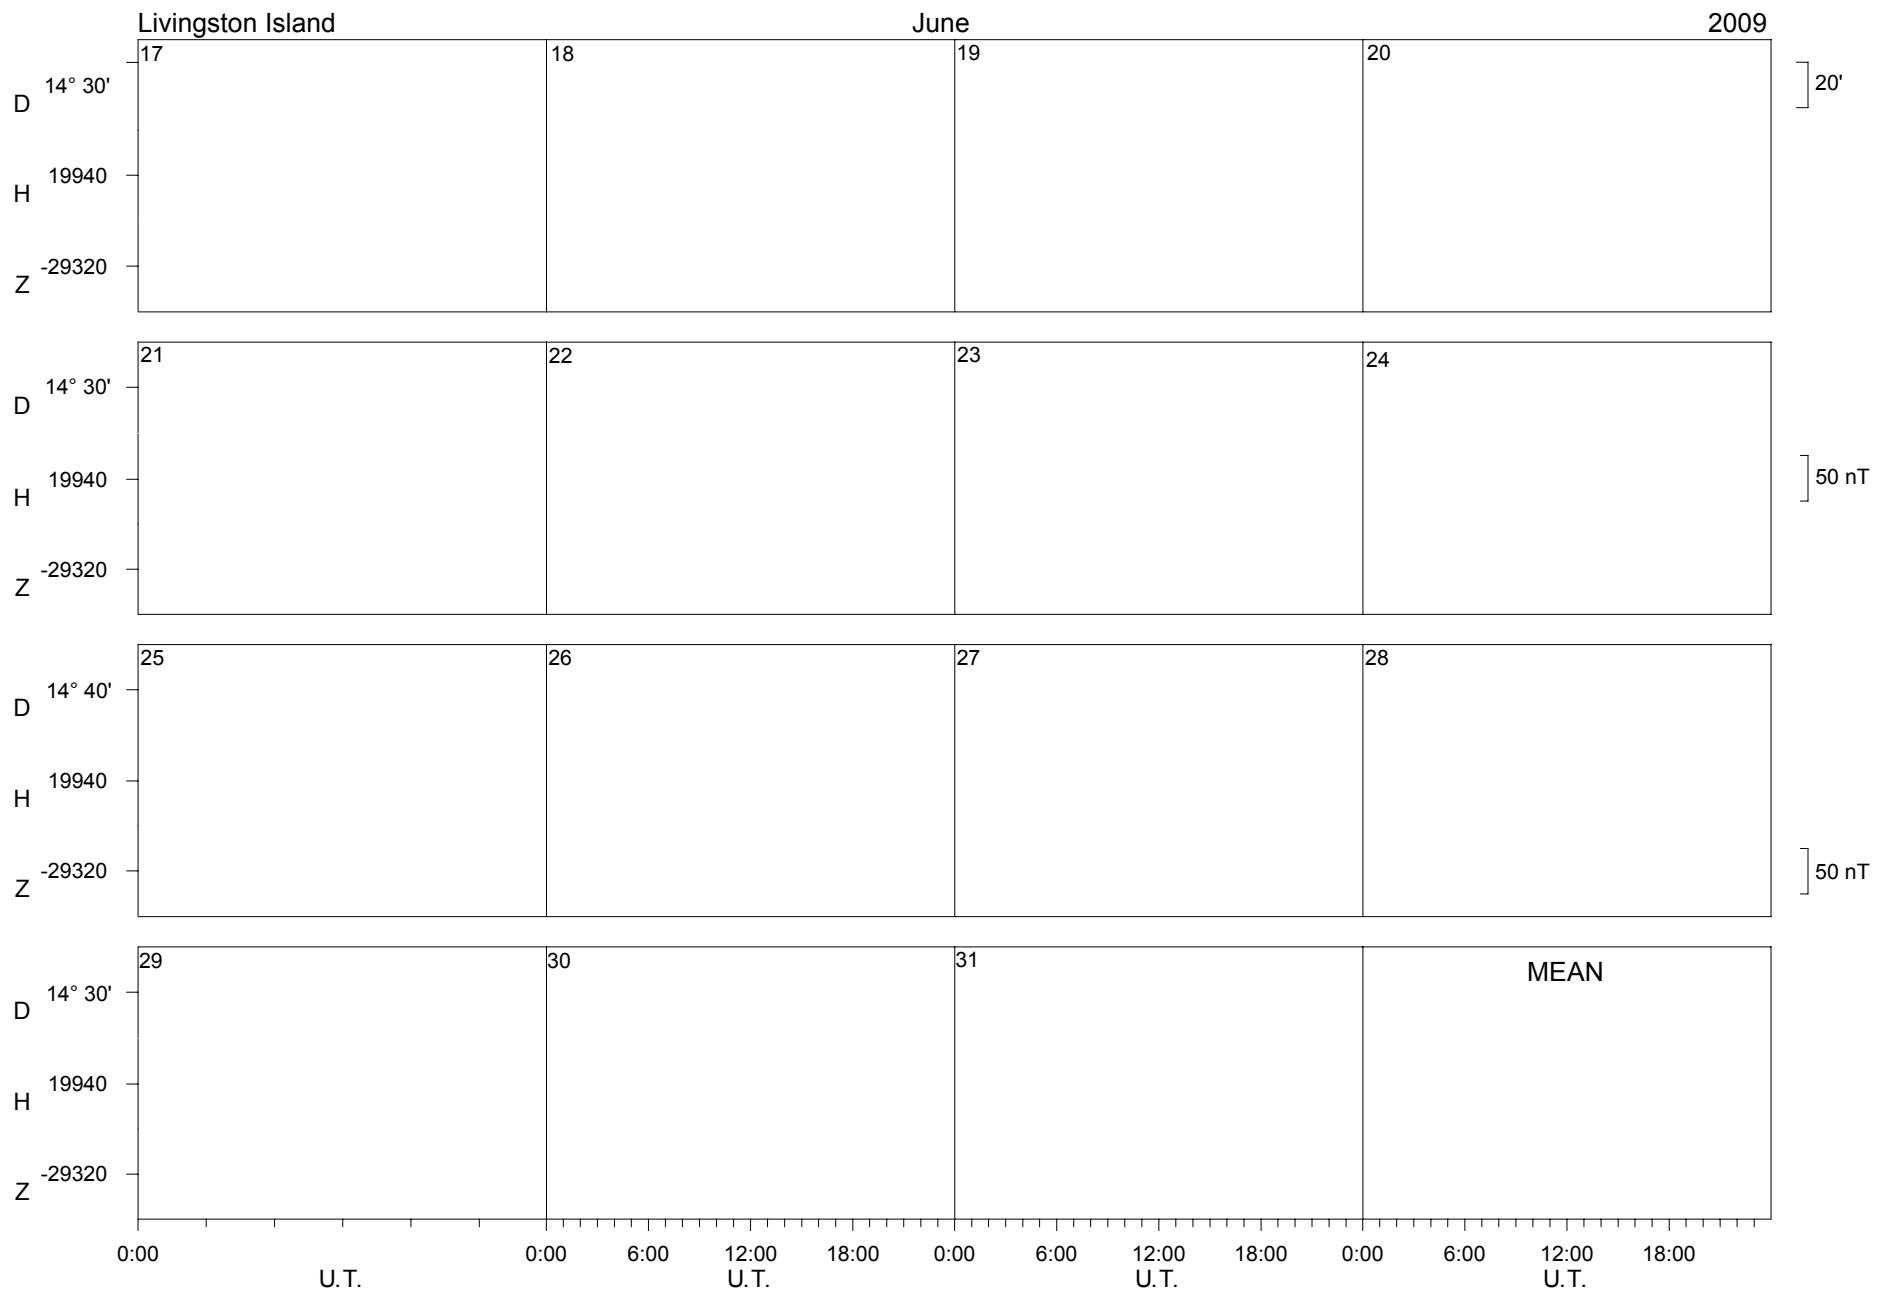

May

2009

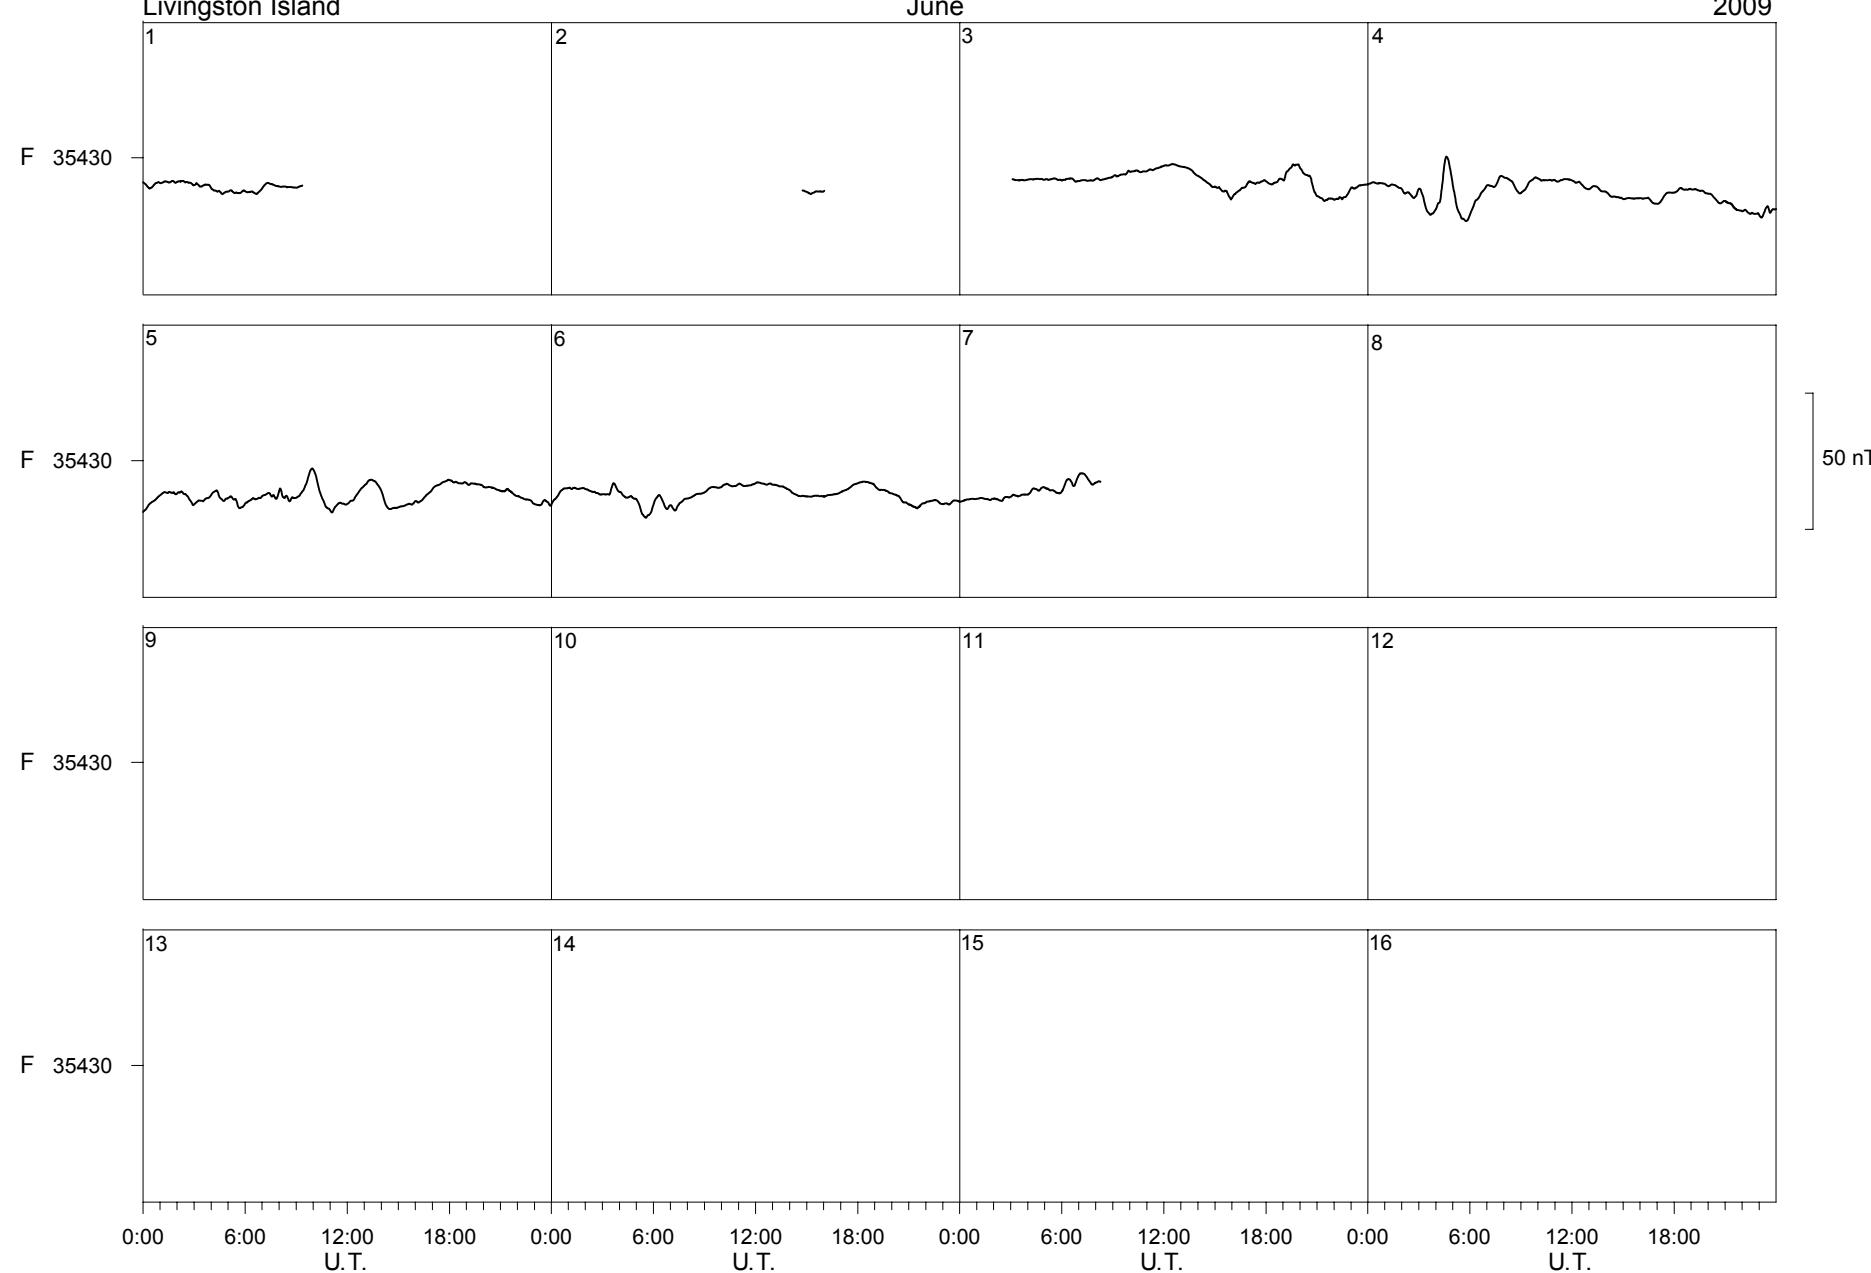

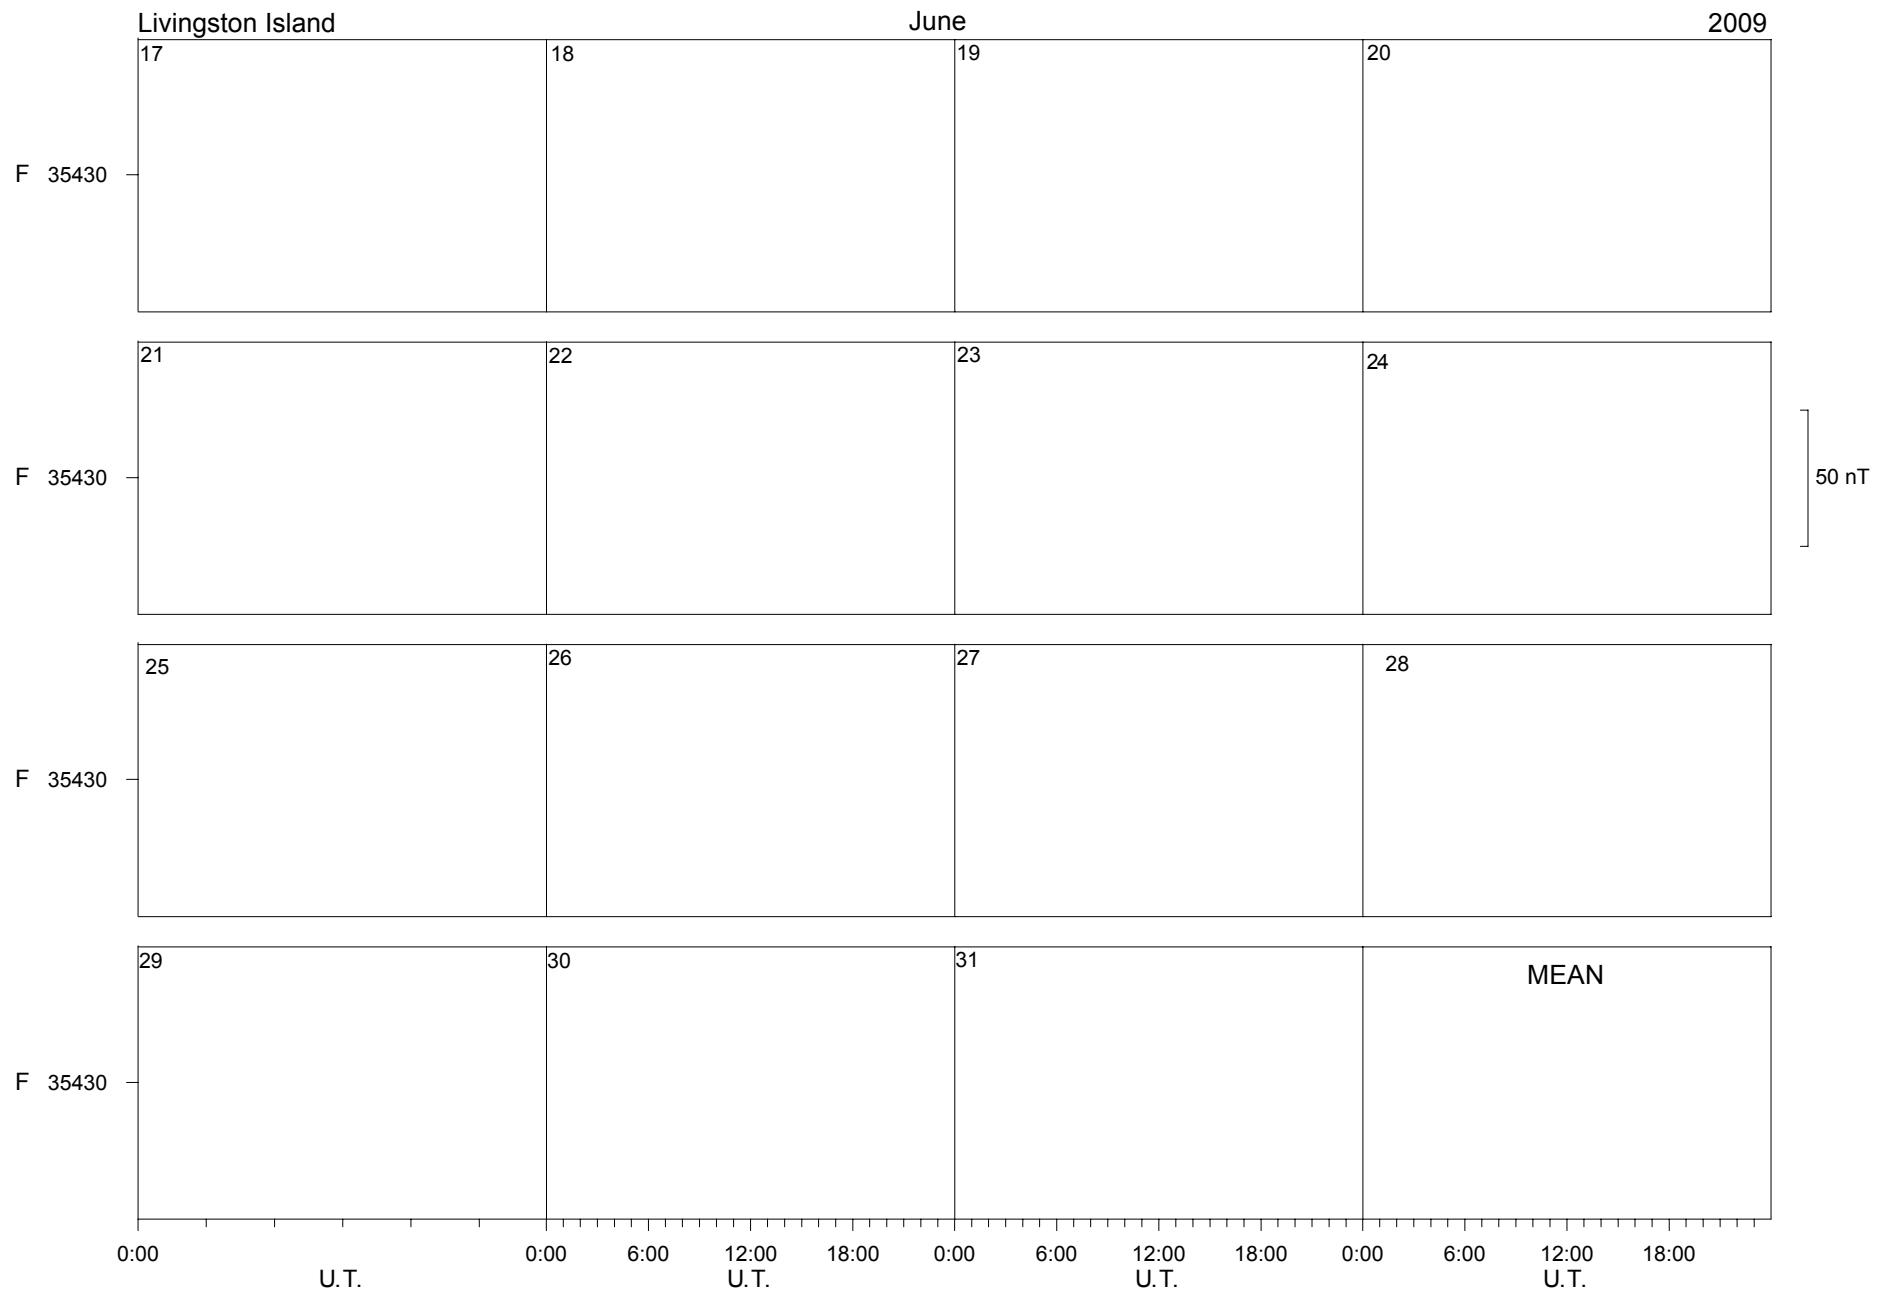

Livingston Island

June

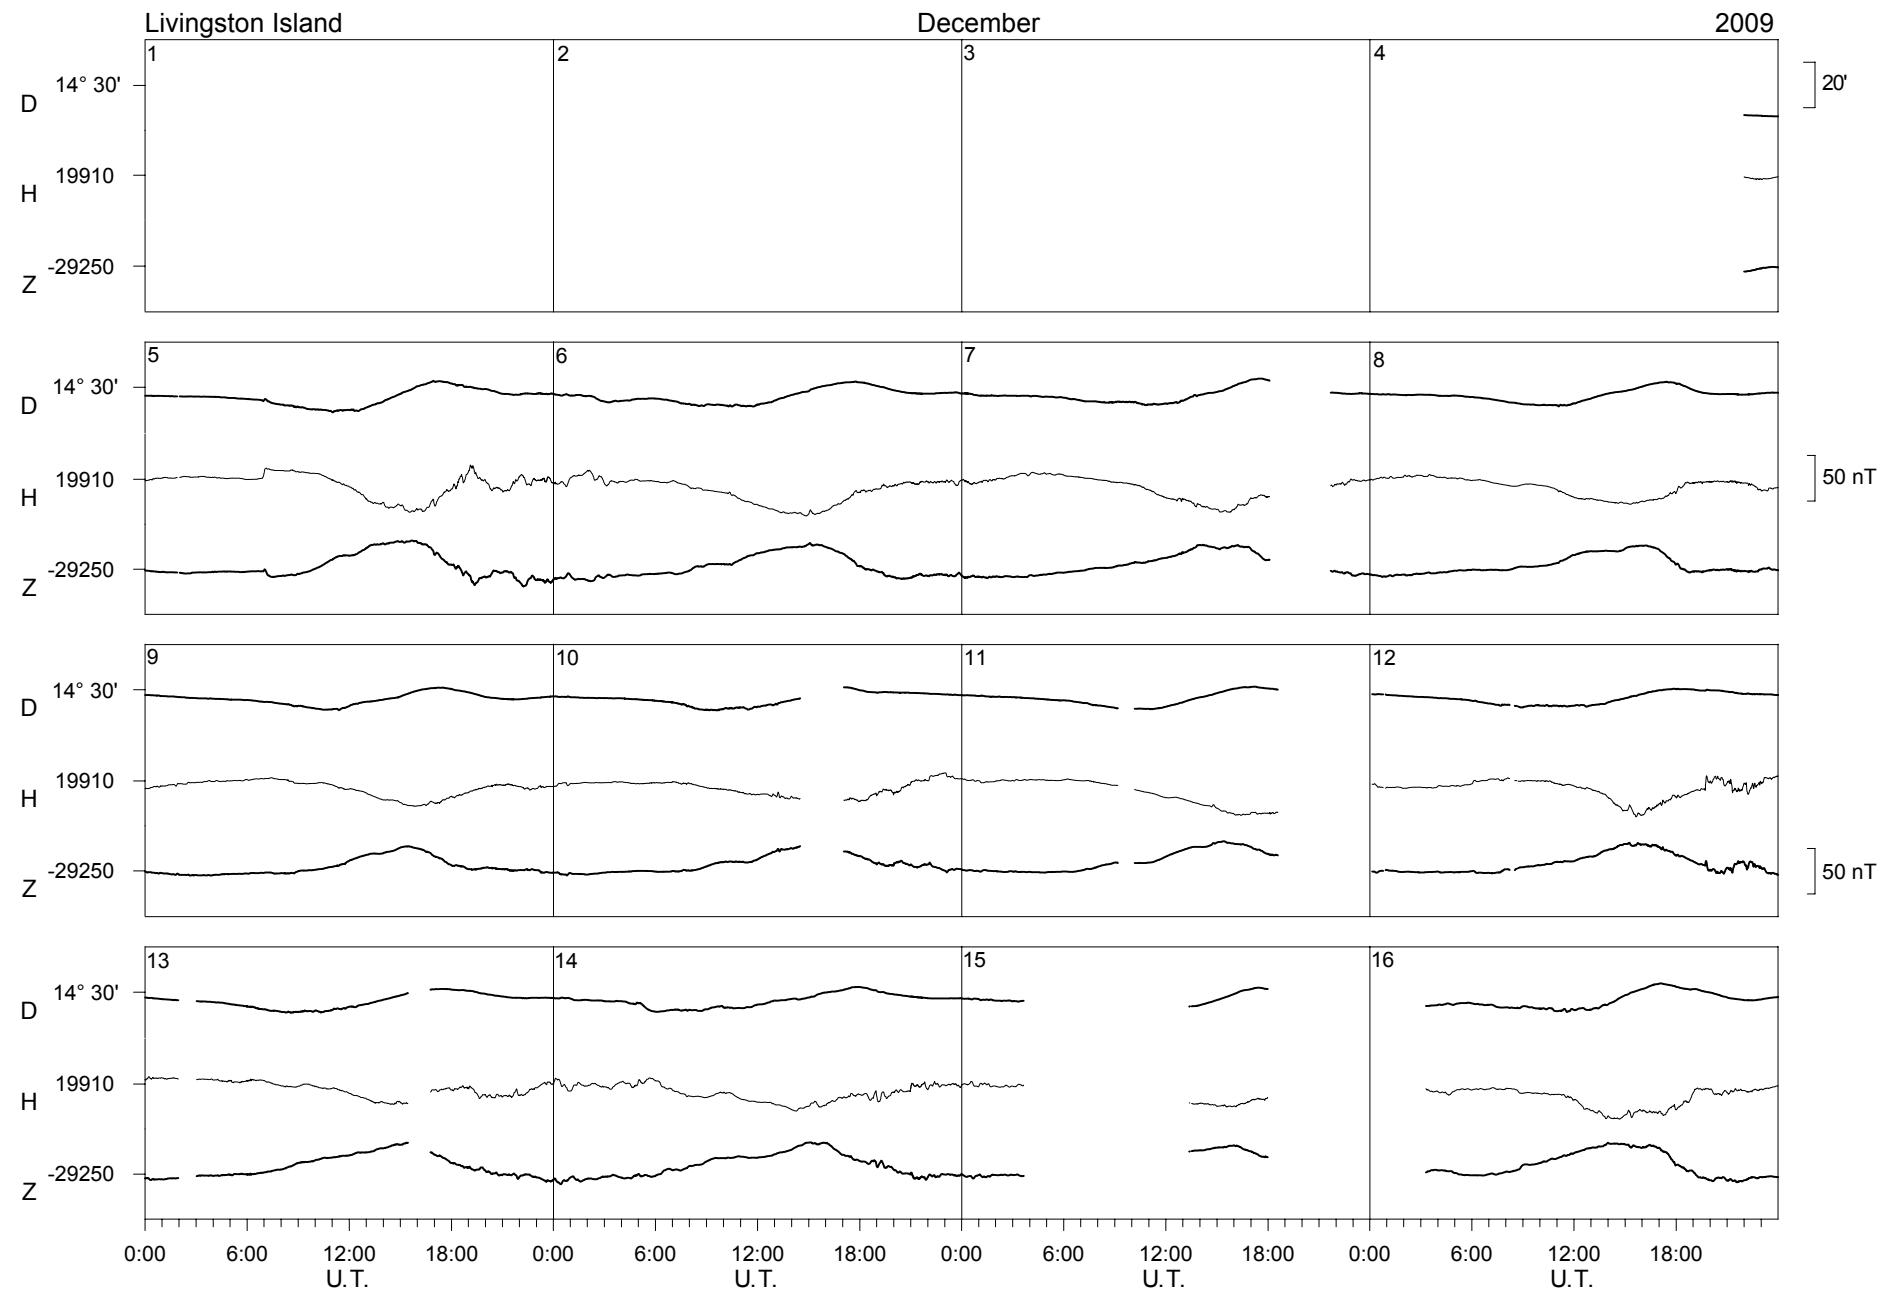

2009

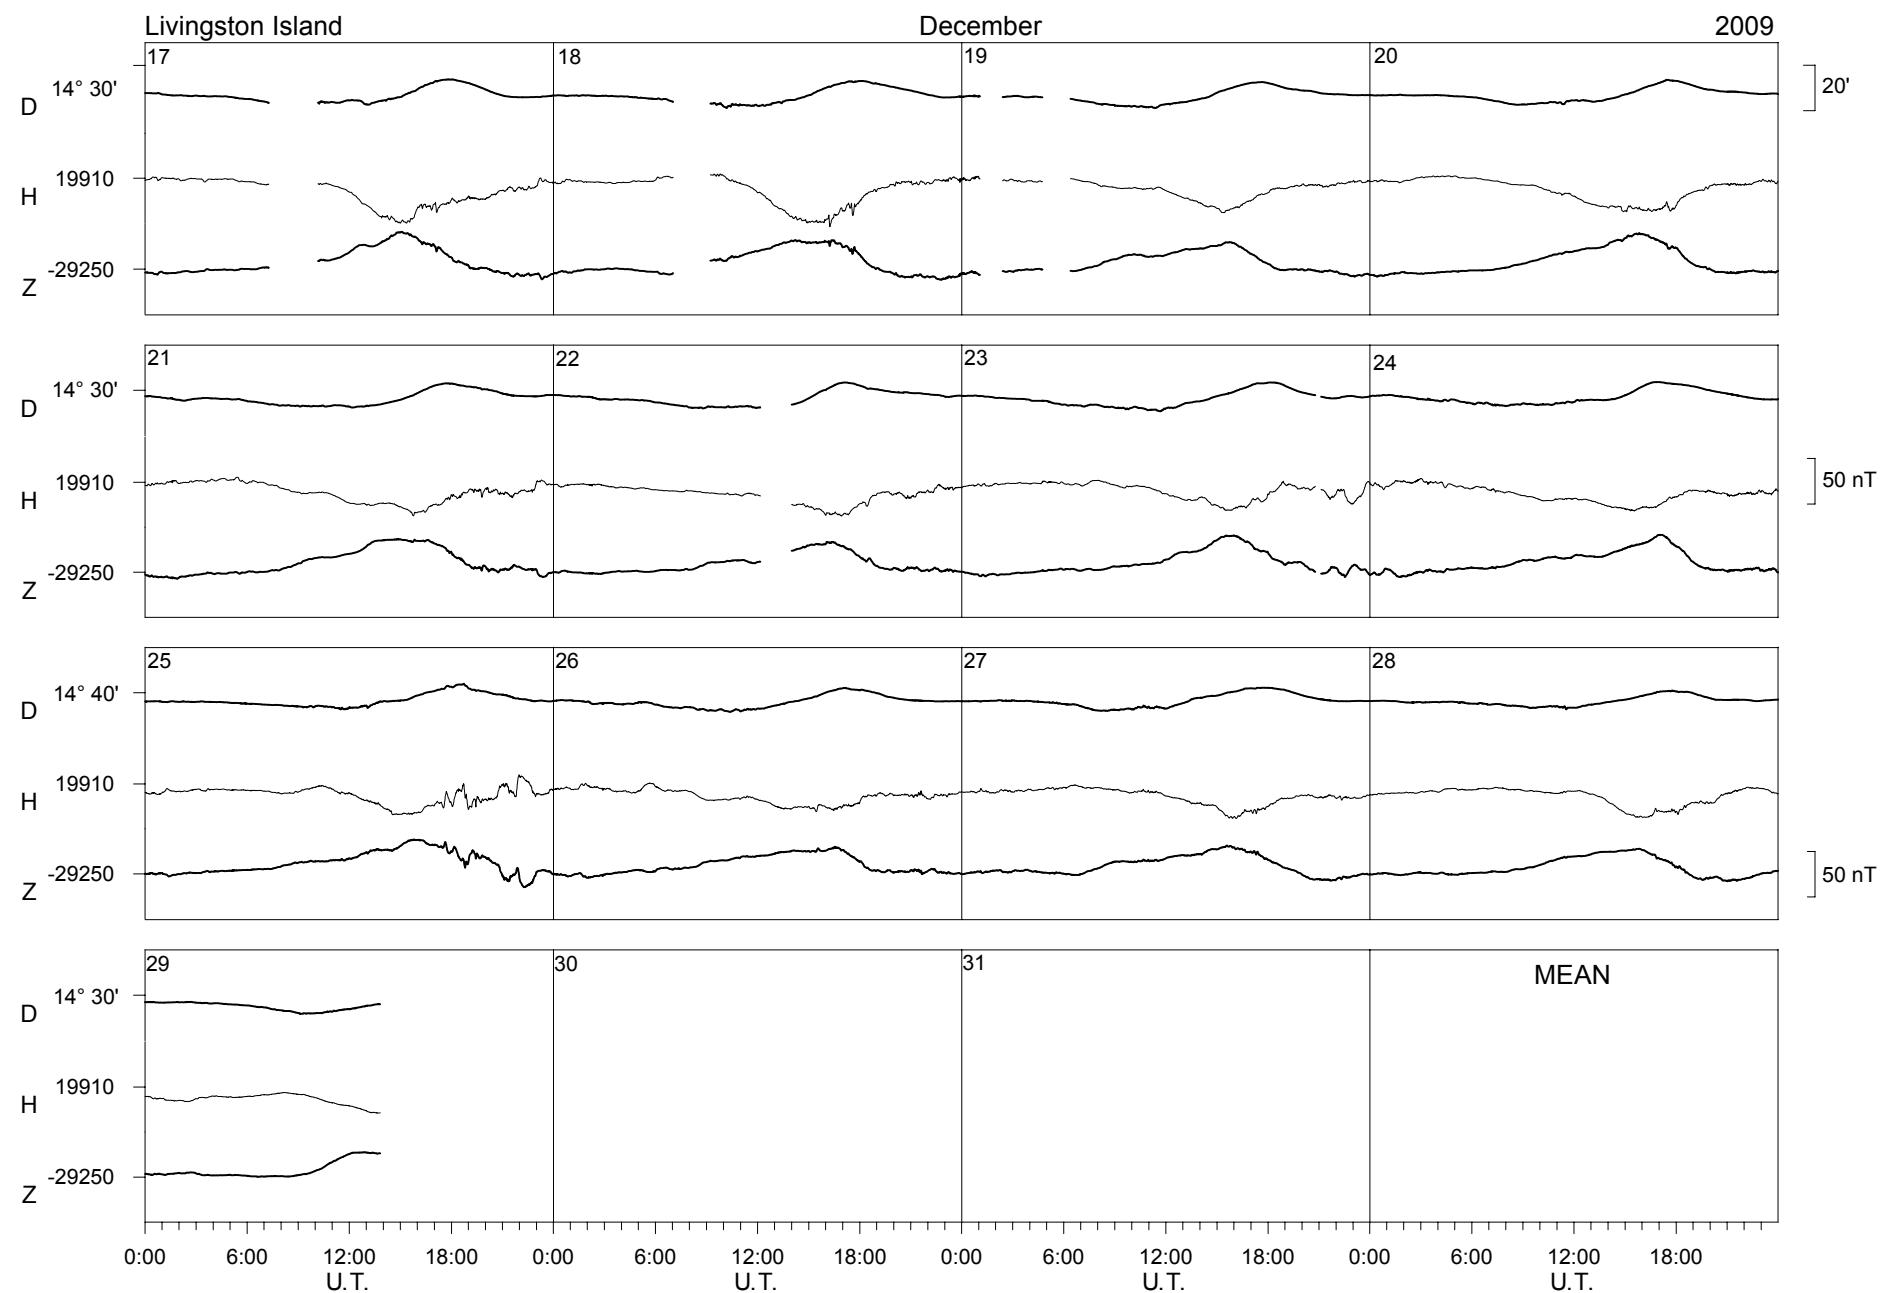

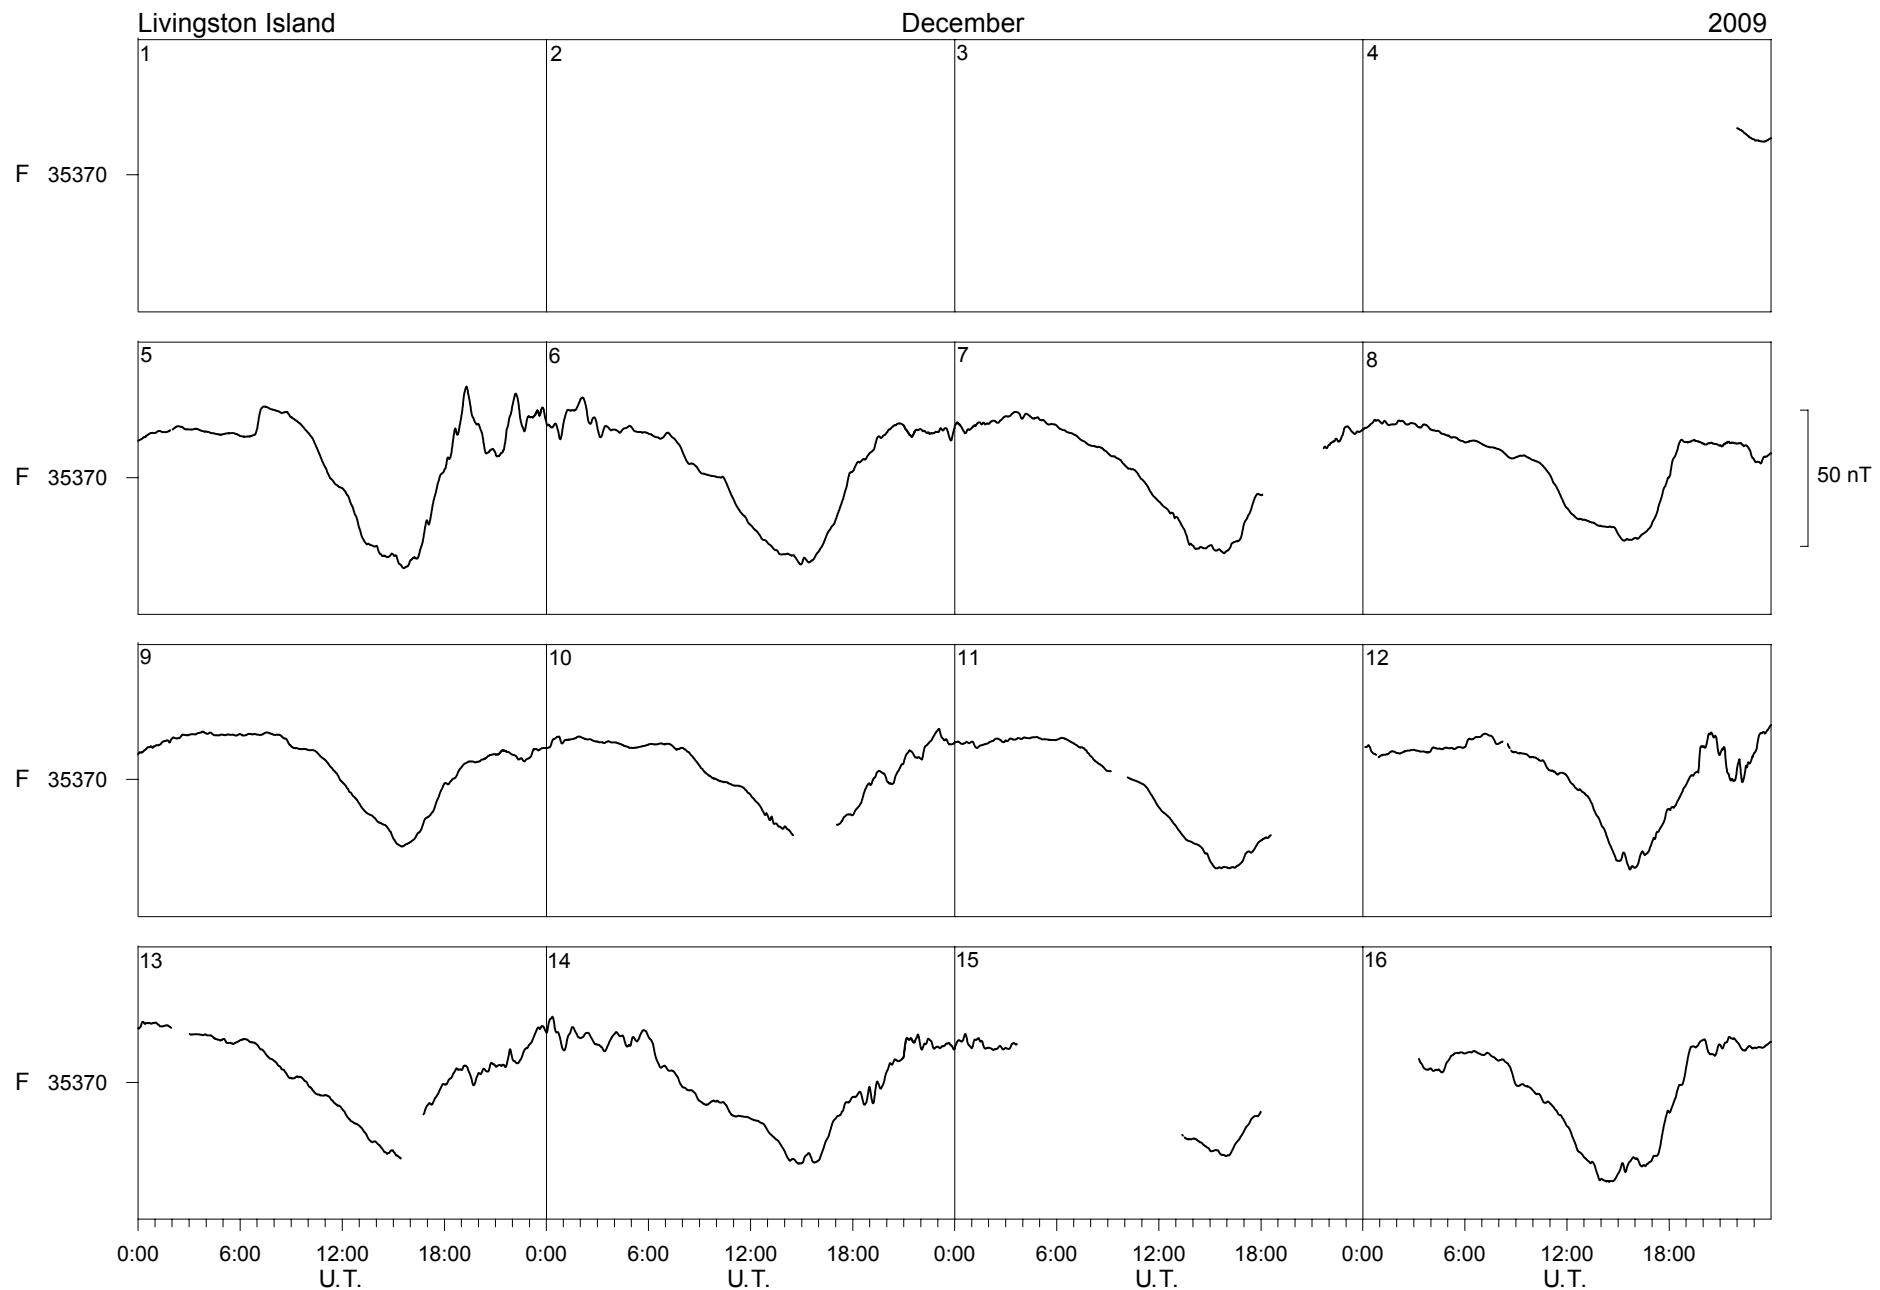

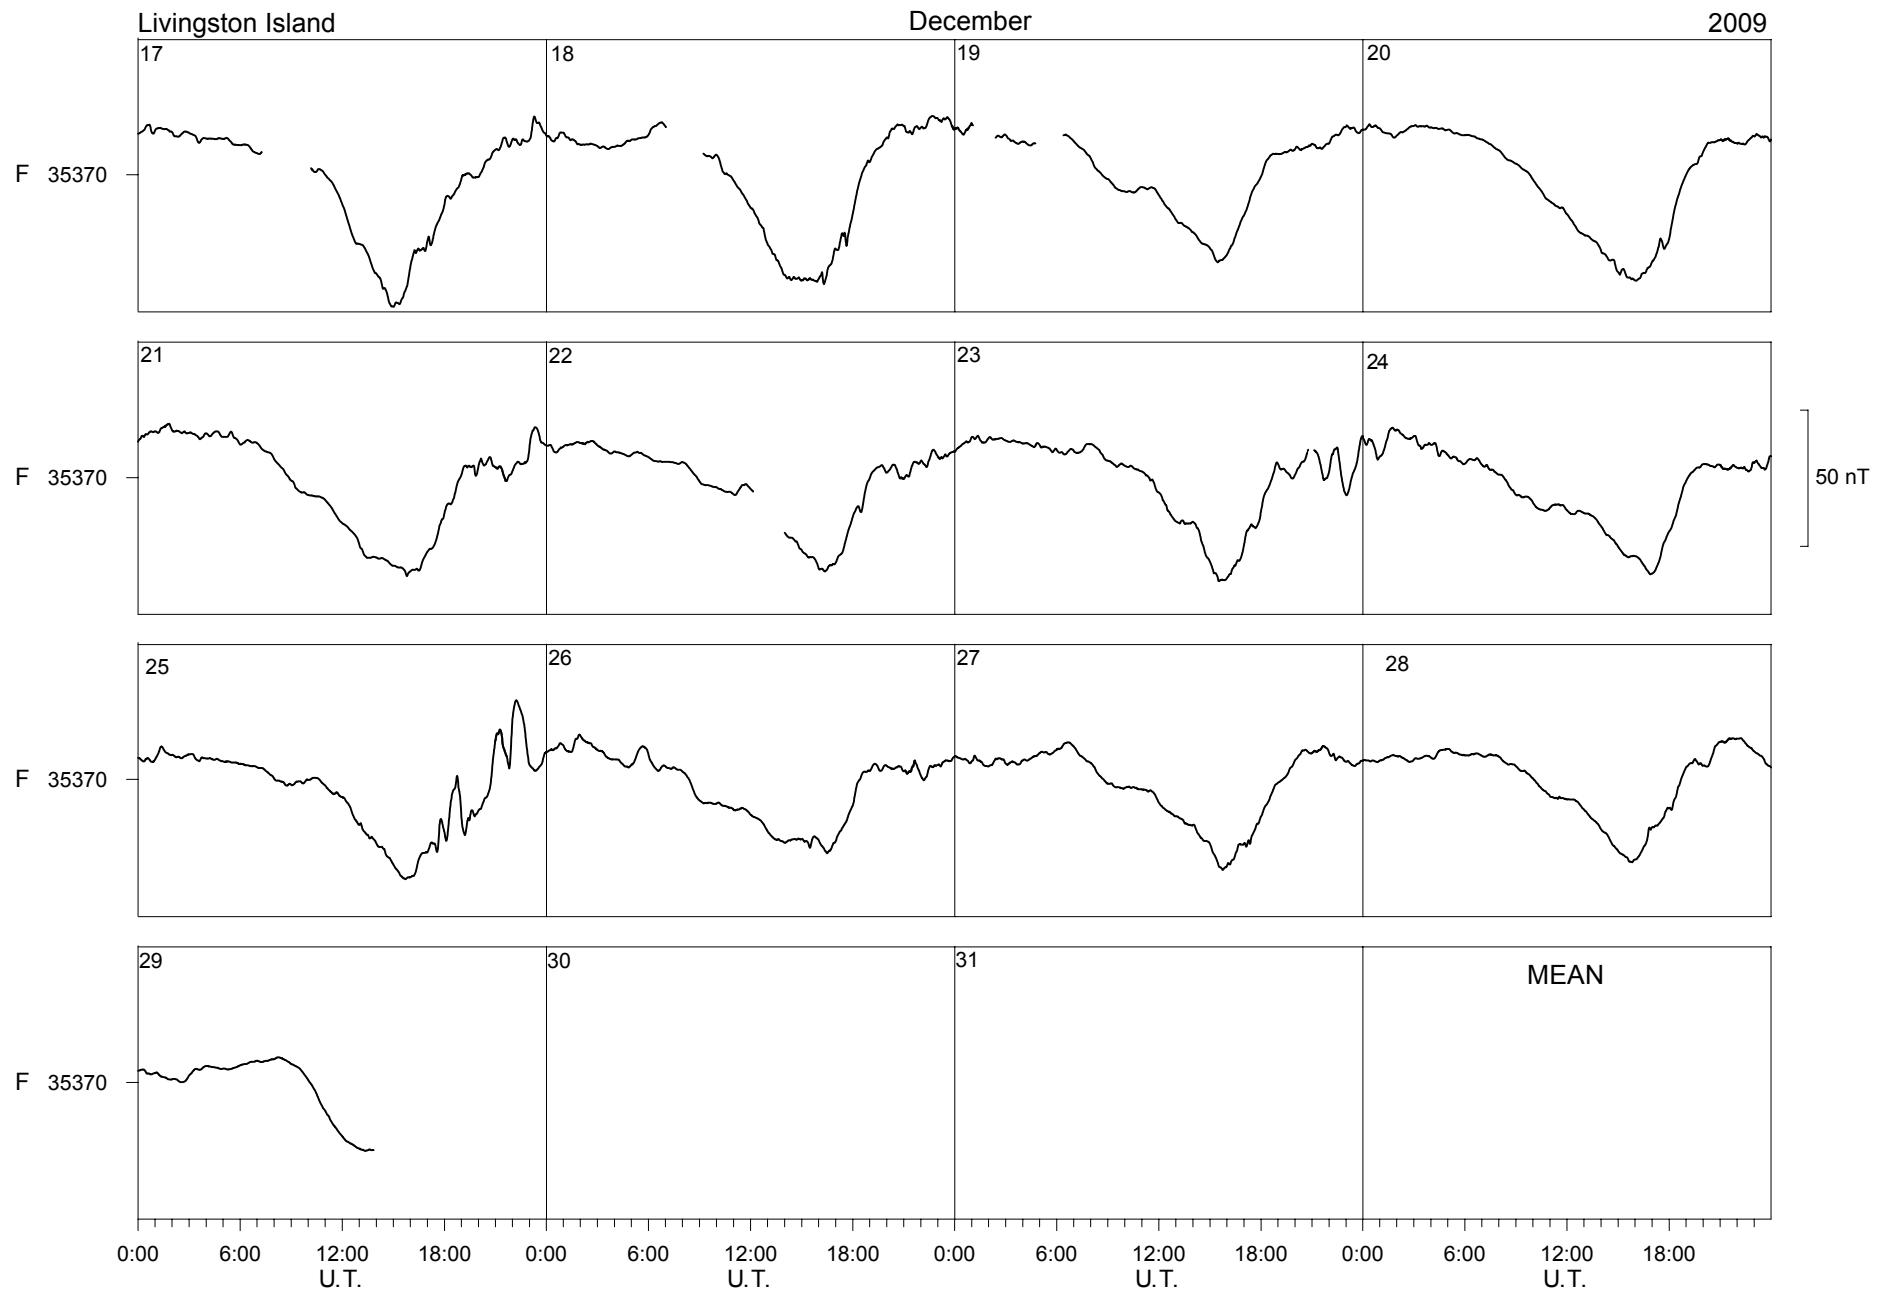

DEBIDO AL DETERIORO DEL SISTEMA DE ADQUISICIÓN DE ENERGÍA DE LA BASE, NO HAY REGISTRO DESDE EL 7 DE JUNIO HASTA EL 4 DE DICIEMBRE, AL INICIO DE LA CAMPAÑA 2009-2010.

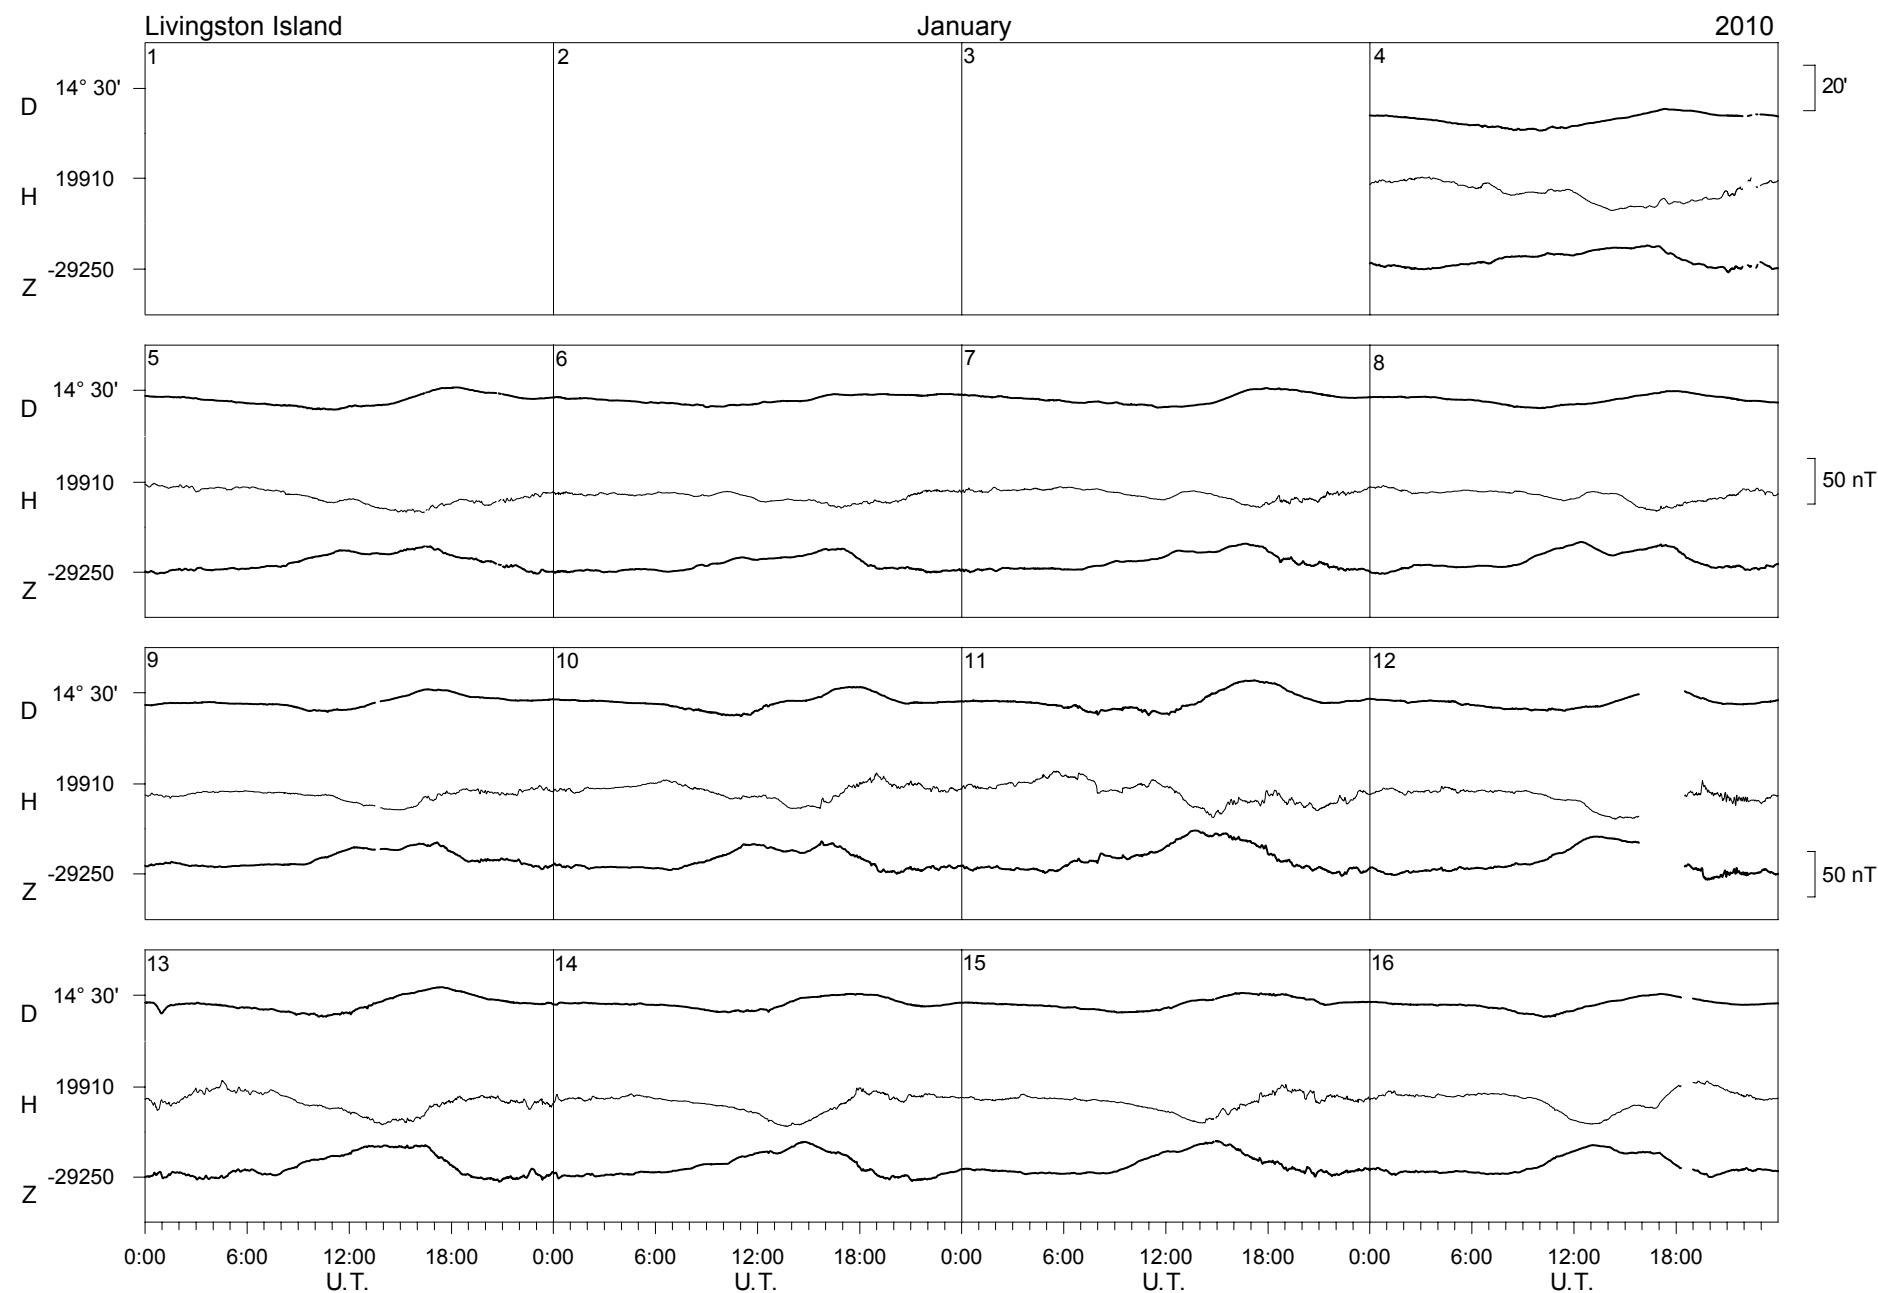

DUE TO PROBLEMS AFFECTING THE ENERGY ACQUISITION SYSTEM IN THE BASE, THERE ARE NO RECORDS FROM JUNE 7th 2009 UNTIL DECEMBER 4th 2009, AT THE BEGINNING OF THE 2009-2010 SUMMER SURVEY.

JUNE 2009

TOTAL INTENSITY

DEBIDO AL DETERIORO DEL SISTEMA DE ADQUISICIÓN DE ENERGÍA DE LA BASE, NO HAY REGISTRO DESDE EL 7 DE JUNIO HASTA EL 4 DE DICIEMBRE, AL INICIO DE LA CAMPAÑA 2009-2010.

DUE TO PROBLEMS AFFECTING THE ENERGY ACQUISITION SYSTEM IN THE BASE, THERE ARE NO RECORDS FROM JUNE 7th 2009 UNTIL DECEMBER 4th 2009, AT THE BEGINNING OF THE 2009-2010 SUMMER SURVEY.
